

# HYDRONOMEAS: A WATER RESOURCES PLANNING AND MANAGEMENT SOFTWARE SYSTEM

European Geosciences Union (EGU) General Assembly,  
Vienna, Austria, 25 - 29 April 2005

Session HS29: *Hydrological modelling software demonstration*

A. Efstratiadis, G. Karavokiros, and D. Koutsoyiannis

Department of Water Resources, National Technical University of Athens

## What is HYDRONOMEAS?

HYDRONOMEAS is an operational tool for the management of **complex water resource systems**. It is suitable to a wide range of hydrosystems, incorporating numerous physical, operational, administrative and environmental aspects of integrated river basin management. The mathematical framework follows the **parameterisation-simulation-optimisation** scheme; simulation is applied to faithfully represent the system operation, expressed in the form of **parametric rules**, whereas optimisation is applied to derive the **optimal management policy**, which simultaneously minimises the risk and cost in decision-making.

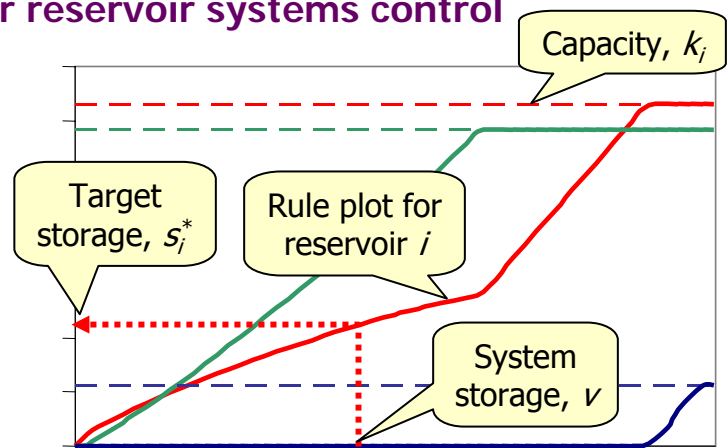

## Main modelling issues

- Employing **stochastic simulation** to handle the inherent **uncertainty** of future inflows and evaluate the system performance in **reliability** terms.
- Establishing a **low-dimensional approach** (by means of parametric operation rules), thus enabling an effective and efficient coupling of stochastic simulation within a water resource system optimisation framework.
- Handling all physical and operational constraints through a **network linear optimisation model**, ensuring a faithful representation of system operation and drastically reducing the computational effort of the simulation procedure.

## Parametric rules for reservoir systems control

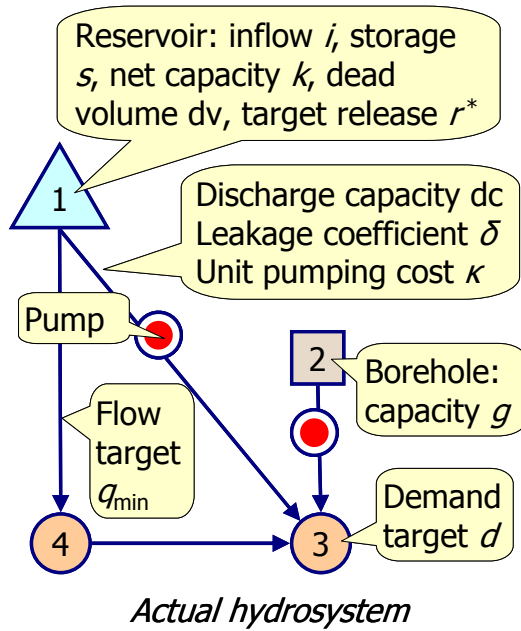

The rules, using two parameters per reservoir  $i$ , specify the corresponding target storage  $s_i^*$  as a function of:

- the actual system storage  $v$
- the total system capacity  $k$
- the capacity of the specific reservoir  $k_i$  (physical constraint)
- the desirable storage fluctuation limits  $s_i^{\min}$  and  $s_i^{\max}$  (operational constraint, user defined)

The parametric rules, introduced by *Nalbantis & Koutsoyiannis (1997)*, have been generalised for the optimal control of both surface and groundwater resources.

## Simulation through a network optimisation model

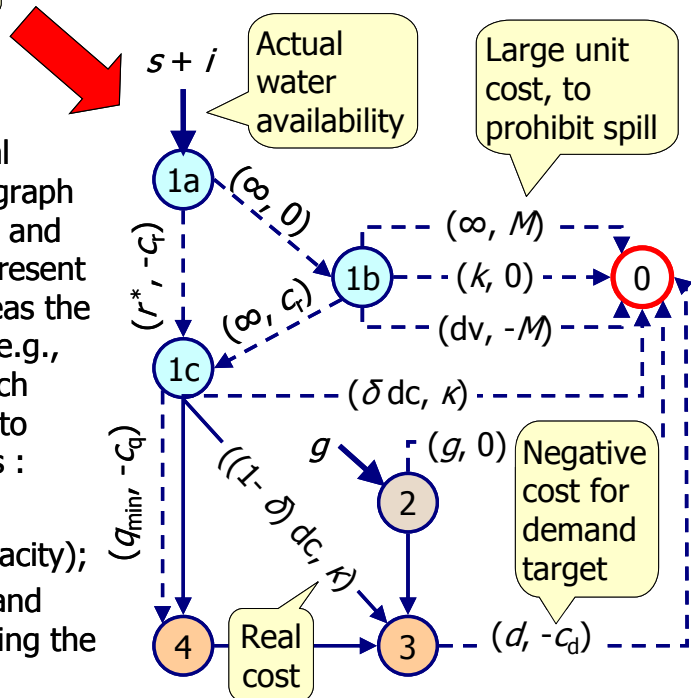

Assuming that inflows are projected through stochastic simulation, the target releases, as specified by the operation rules, may differ from the real ones, due to at least one of the following reasons:

- insufficient discharge capacity of the downstream aqueduct network;
- existence of alternative flow paths, with different costs (e.g., due to pumping);
- existence of multiple and contradictory water uses and operational constraints;
- insufficient inflows to fulfil demands or insufficient capacity to store flood runoff.

To evaluate the optimal fluxes, real components are transformed to digraph components, and virtual capacities and costs are assigned; the former represent target abstractions or flows, whereas the latter penalise undesirable fluxes (e.g., spill) and preserve priorities. At each time step a LP problem is formed, to achieve the following requirements :

1. strict satisfaction of all physical constraints (storage & flow capacity);
2. satisfaction of demand targets and operational constraints, preserving the user-defined priorities;
3. minimisation of departures between actual and target abstractions;
4. minimisation of transportation costs.

*Digraph model representation; dotted lines represent virtual arcs, with capacity and unit cost in parenthesis.*

# The parameterisation – simulation – optimisation methodological framework

## Step 1: Hydrosystem data

System components and technical characteristics

Water uses and priorities, operational constraints

Inflow time series (historical, real time)

Stochastic simulation of hydrological processes

Synthetic inflows

## Step 2: Parameterisation

Parametric expression of hydrosystem management policy (operation rules, for surface- and groundwater resource control systems)

## Step 3: Problem statement

Control variables (parameters)

Constraints (in probabilistic terms)

Performance measure (cost, reliability, safe yield)

## Step 4: Problem solution

Update of control variables

Simulation procedure

Digraph representation of real system components and targets

LP model solution (simplex method)

Step-by-step evaluation of optimal costs and fluxes, constraint handling

Evaluation of system performance

Global optimisation through the evolutionary annealing-simplex algorithm

## Step 5: Optimal solution

Operation rules

System reliability

Stochastic forecast of water availability and abstractions

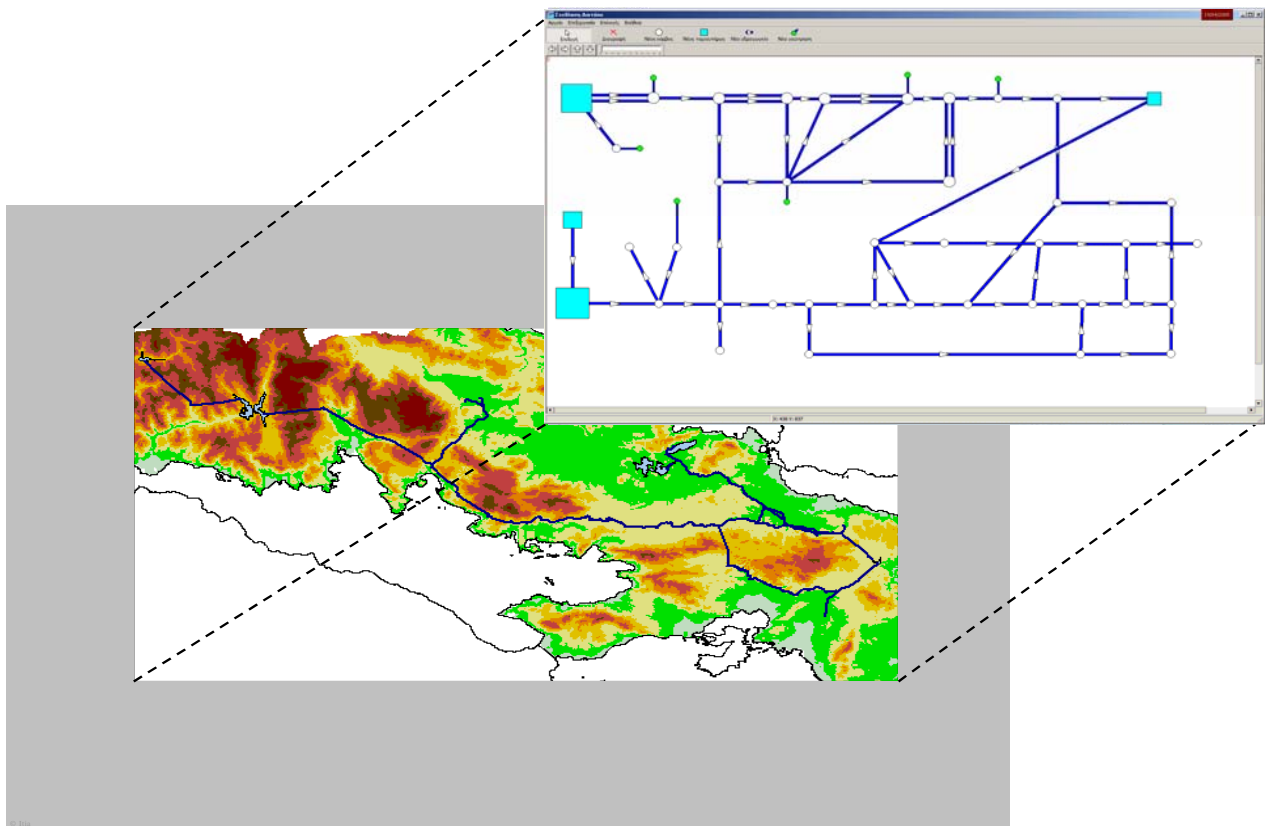

## Step 6: Decision making

Strategic planning and management

## HYDRONOMEAS gives answers to questions such as:

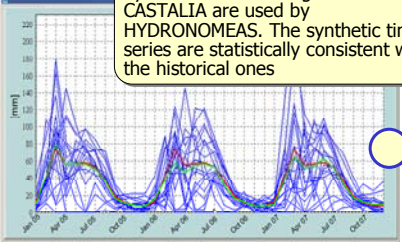

- What is the **maximum total withdrawal** from the hydrosystem, for a given hydrologic regime and a given reliability level?
- What is the **minimum failure probability** in achieving a given set of operational goals, for a given hydrologic regime?
- What is the **minimum cost** to achieve a given set of operational goals, for a given hydrologic regime and a given reliability level?
- What is the **maximum benefit** from energy production?
- Which will be the **water availability** for a short-term time horizon?
- What are the impacts of different **management policies** or **hydroclimatic scenarios**?
- How could the system respond to **special occasions** such as channel damages or an intense increase of water demand for a specific period?
- What are the consequences of specific **modifications** in the hydrosystem (e.g., construction of new projects)?

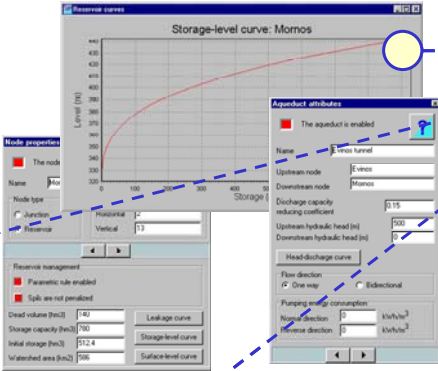

## Schematisation

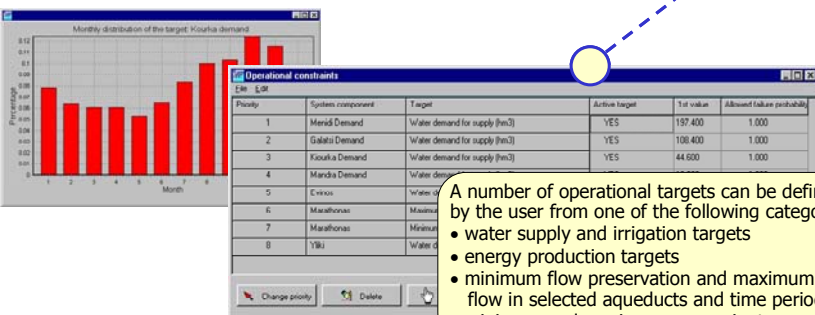

## Scenario data

Synthetic time series generated by CASTALIA are used by HYDRONOMEAS. The synthetic time series are statistically consistent with the historical ones

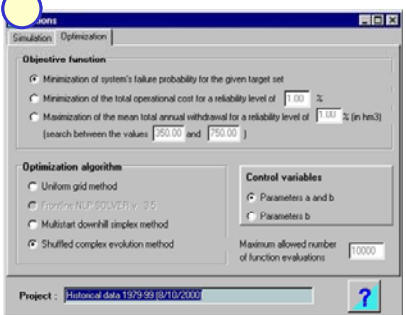

- Network attributes
- Hydrological data
- Operational goals (targets)
- Simulation and optimisation options

Priority	ID#	System component	Target	Active target	T of value	Allowed failure probability
1		Mardi Demand	Water demand for supply (m <sup>3</sup> )	YES	157,400	1,000
2		Galatia Demand	Water demand for supply (m <sup>3</sup> )	YES	108,400	1,000
3		Koukia Demand	Water demand for supply (m <sup>3</sup> )	YES	44,600	1,000
4		Mardi Demand	Water demand for supply (m <sup>3</sup> )	YES	157,400	1,000
5		Ennos	Water demand for supply (m <sup>3</sup> )	YES	108,400	1,000
6		Marathonas	Minimum	YES	108,400	1,000
7		Marathonas	Minimum	YES	108,400	1,000
8		Yliki	Water demand for supply (m <sup>3</sup> )	YES	108,400	1,000

A number of operational targets can be defined by the user from one of the following categories:

- water supply and irrigation targets
- energy production targets
- minimum flow preservation and maximum flow in selected aqueducts and time periods;
- minimum and maximum reservoir storage.

**Objective function**

- Minimization of system's failure probability for the given target set
- Minimization of the total operational cost for a reliability level of [ 1.00 ] %
- Maximization of the mean total annual withdrawal for a reliability level of [ 1.00 ] % (in ha·h)

**Optimization algorithm**

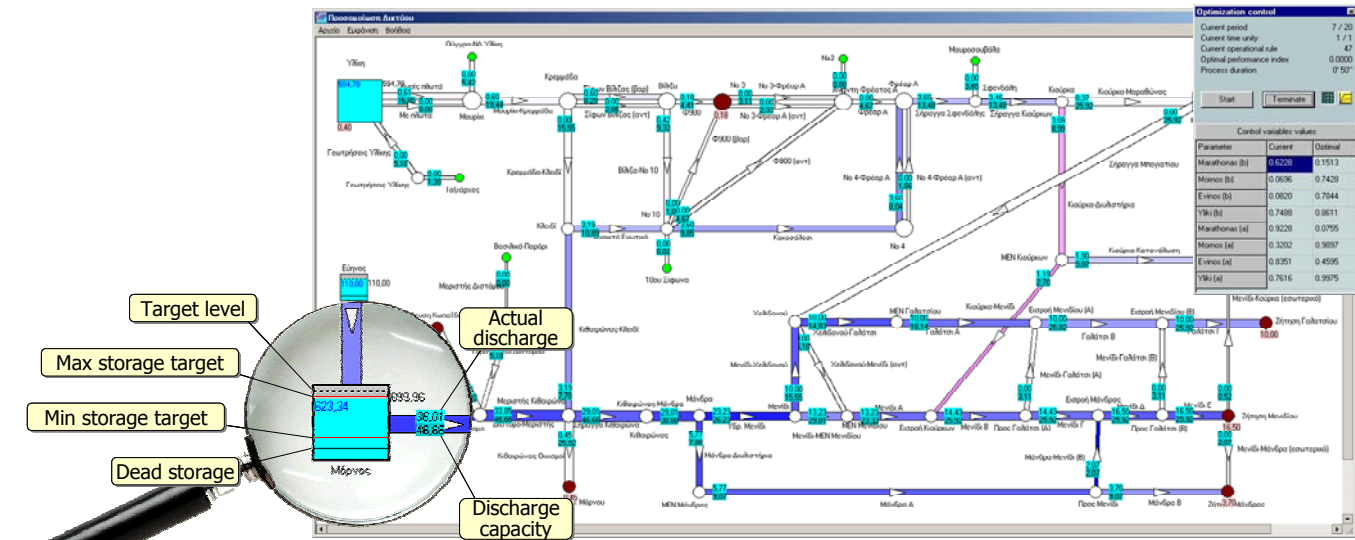

- Uniform grid method
- FORTRAN SOLVER v. 3.5
- Multistart downhill simplex method
- Shuffled complex evolution method

**Control variables**

- Parameters a and b
- Parameters b

Maximum allowed number of function evaluations: 10000

## Simulation

Target level

Max storage target

Min storage target

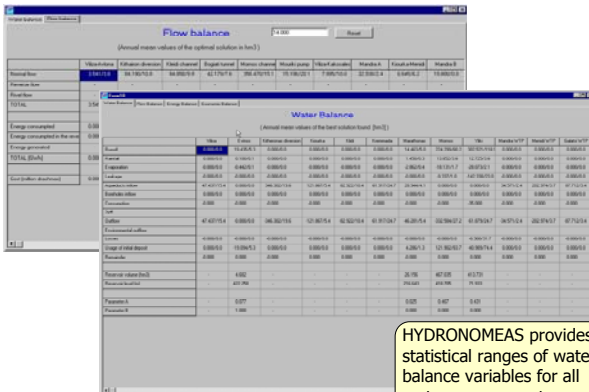

Dead storage

Actual discharge

Discharge capacity

Step by step visualisation of the simulation process

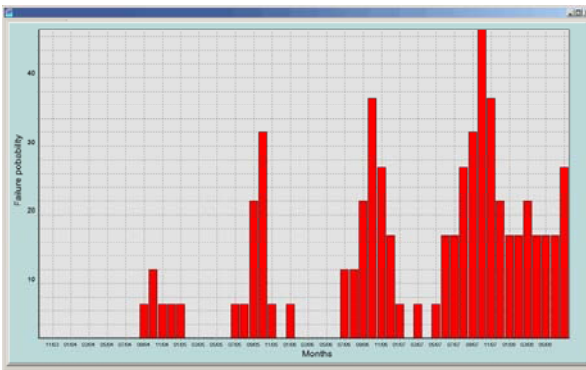

## Results

Analytical water, flow and energy balance

Reservoir operating rules (after optimisation)

Distribution of the failure probability for given targets

Surface water resources storage predictions
